A New CPU Breakthrough Promising 100x Efficiency

<https://www.youtube.com/@TechTechPotato>

EFFICIENT COMPUTER: FABRIC - DATAFLOW No program counter. Instruction wakes up when Waits for information to arrive. The Tile fires when the information arrives, A general purpose CPU that's not just an increment from the last one .

Has working silicon. A Grid of small compute tiles. Waits for information to arrive. Tile fires, no scheduler. Instructions wake up when data arrives.

ENERGY EFFICIENT COMPUTING. E1 - FABRIC

Claims to be between 10 and 100 x more efficient than leading low-power CPUs. (Compares to various ARM chips)

Operations per Joule: how much work: Instructions per second per watt

Key metric TOPS per Watt. Energy matters more than peak throughput. Efficient have crossed the line between research into prototype. Shown at CES this year.

Efficient Computer's Fabric processor architecture

Offers a compelling advantage over typical processors relying on fixed-purpose accelerators paired with general-purpose core. While specialized hardware like ASICs excel at specific computations (e.g., certain machine learning tasks), they are limited by Amdahl's Law: a system is bottlenecked by the part left unoptimized.

As applications evolve, or demand diverse algorithms (e.g., a mix of signal processing and AI/ML), only a fraction of the workload may fit the fixed accelerator. The remaining code must then execute on a less efficient, general-purpose core, eroding significant energy gains. This often leads to premature obsolescence and high non-recurring engineering costs for ASICs and processors with a host of fixed-purpose accelerators as application requirements shift.

Conversely, the Fabric is a general-purpose programmable processor designed to efficiently handle the entire application. Its spatial dataflow architecture adapts seamlessly to a wide spectrum of algorithms. This eliminates the need for multiple specialized solutions, making it broadly applicable across industrial automation, wearables, and satellite systems. By dramatically improving the energy efficiency of active computation for the complete workload, the Fabric avoids performance bottlenecks and enables multi-year battery lifetimes, even as applications evolve.

Videos about computers. And people of tech.

[NEXT PAGE]

YouTube creators cover tech hardware, semiconductors, chip design, AI advancements, physics, math, and related curiosities (with an educational or explanatory bent), here's additional channels that align well with the Chiplet Summit. These suggestions emphasize independent creators or small teams producing in-depth, insightful content suitable for a panel on future AI technology, chiplets, and emerging tech. I've prioritized those not already listed in the document, grouped them thematically, and included approximate subscriber counts as of 2025 for context.

Semiconductor and Chip Design Explainers

Asianometry (~750K subscribers): Deep dives into semiconductor manufacturing, chip history, and global supply chains (e.g., videos on TSMC's processes or Moore's Law limits). Fits for discussing chiplet evolution and AI hardware constraints.

Anastasi In Tech (~250K subscribers): A chip engineer breaking down semiconductor tech, AI chips, and industry trends like EUV lithography or quantum dots. Ideal for technical yet accessible insights on tomorrow's AI tech.

Sam Zeloof (~150K subscribers): Documents homemade semiconductor fabrication in a garage lab, covering photolithography and chip building from scratch. Adds a hands-on, innovative angle to chiplet discussions.

High Yield (~120K subscribers): Analysis of chip news, architecture comparisons, and semiconductor market shifts (e.g., AMD vs. Intel chiplets). Great for high-level hardware reasoning without consumer fluff.

Hardware and Digital Electronics Builders/Educators

Ben Eater (~800K subscribers): Builds and explains breadboard computers, digital logic, and low-level hardware like CPUs from basic components. Complements the proposal's tech curiosities with foundational hardware education.

Robert Feranec (~150K subscribers): Interviews with hardware engineers on PCB design, signal integrity, and advanced electronics for AI systems. Aligns with practical aspects of chiplet integration and AI tech.

Branch Education (~1.2M subscribers): 3D animations explaining how hardware works inside (e.g., smartphone SoCs or SSDs). Visual style similar to 3Blue1Brown but focused on physical tech, perfect for inspiring summit attendees.

AI and Computer Science Focus

Two Minute Papers (~1.5M subscribers): Quick summaries of cutting-edge AI research papers, often touching on hardware implications like neural networks on GPUs. Echoes the AI Revolution channel's vibe for forward-looking AI tech.

Computerphile (~2.3M subscribers): Expert talks on computer science topics, including algorithms, AI ethics, and hardware like quantum computing or parallel processing. Broadens the physics/AI overlap seen in Sabine Hossenfelder or Veritasium.

Coreteks (~100K subscribers): In-depth breakdowns of CPU/GPU architectures, AI accelerators, and semiconductor roadmaps (e.g., next-gen chiplets). Suited for panel debates on AI's hardware future.

These channels share the proposal's "luminaries" ethos—educational, thought-provoking content from passionate creators that could roam events, sign autographs, or join panels. They avoid purely consumer-review styles, emphasizing reasoning, innovation, and tech depth to inspire on topics like AI's role in chiplets. If subscriber growth or relevance shifts, checking current metrics on YouTube would confirm fit.

THIS IS AN OPPORTUNITY FOR A NEW MARKETING CHANNEL FOR THE CHIPLET SUMMIT
